Limbus Company Turn-Based Combat System

Doney Tran | doney2@pdx.edu | github repo soon?

It sort of fits the simulation theme, but I don't really think it is emergent so I will opt out unless I am able to implement different personalities for the test AI's which will act depending on different components like health, speed, status effects, etc. I think that exhibits emergent behavior.

Above is the game and I want to see if I can build some of those parts. I don't really think there is a guide or tutorial for this and even then I still really want to build it myself and see how the systems I see in other games work, that is my biggest goal.

Approach

1. I think I'll start simple by defining a character. They have the usual hp and also statuses that can be applied to them. There are also a few more special ones like sanity, and stagger tied to each of them. Special triggers happen when they hit certain numbers.
2. I will probably move on to how characters can interact with each other, it depends on speed and some other factors like if they have been stunned by a skill or staggered when their bar goes too low. You can see the targeting with the arrows in the example. The turn system is also something I will need to work on since there are many different orders of things being able to happen.
3. Create the enemy personalities/AI and randomly generate some so that each fight is different. In one fight, enemies may all have the trait that they target the lowest hp character or one of them may like to boost their team up.
4. If I'm able to get through all of that I don't really expect at all because I will be trying to learn Rust and messing up while also trying to create a game system where I have absolutely no

experience aside from playing these systems for a long long time, I wanted to use the Bevy engine, which is a game engine written in Rust to render and display everything instead of trying to do it in a terminal.

Concerns

1. I may be biting more than I can chew since this will be learning Rust, but also building a system from scratch. It is a big challenge, but I would like to keep myself decently motivated and busy.
2. I think my realistic goal is getting to number 2 so I may not really have met all the things I wanted to do.
3. I have a capstone to complete and I don't really know how much time that will eat as the project I am working on has new languages I have never worked with and also working professionally for the first time.

You made it to the end! 🎉
